Chp - 1

P7 Given:

Propagation delay - 10 ms ①

Transmission : 2 mbps (mega bits per second)

Analog \rightarrow Digital Conversion speed = 64 Kbps

Packet sent = 56 byte
= 56 \times 8
= 448 bits

• Packet tran time

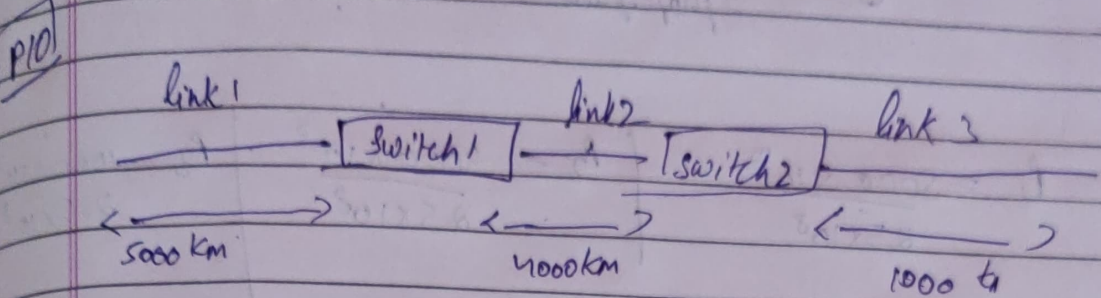

2mb - 1s
448b - 1

$$\frac{448}{2 \times 10^6} = 0.224 \text{ ms}$$

• Analog \rightarrow digital time ~~200~~

$$\begin{array}{l} 64 \text{ Kb} - 1\text{s} \\ 448 \text{ b} \rightarrow 1 \end{array} \quad \rightarrow \quad \frac{448}{64 \times 10^3} = 7 \text{ ms}$$

Total time = ① + ② + ③
= 17ms

Given:

Size of Packet = 1500 bytes
= 1500×8 bits

Prop Speed = 2.5×10^8 m/s
Trans speed = 2×10^6 bits/s

Processing time = 3ms

$l_1 = 5000 \times 10^3$ m, $l_2 = 4000 \times 10^3$ m, $l_3 = 1000 \times 10^3$ m

- There are 2 switches
Total Packet switch processing Delay
= $3\text{ms} \times 2$
= 6ms

Trans. delay = $\frac{\text{Total bits}}{\text{Trans. rate}} = \frac{1500 \times 8}{2 \times 10^6}$
= $6000 \times 10^{-3} = 6\text{ms}$, Total trans = 6×3
= 18ms

$$\rightarrow \text{Prop delay} = \frac{\text{distance}}{\text{prop speed}}$$

$$P_1 = \frac{5000 \times 10^3}{25 \times 10^8}$$

$$= 2 \times 10^{-2} \text{ s}$$

$$= 20 \text{ ms}$$

$$P_2 = \frac{4000 \times 10^3}{2.5 \times 10^8}$$

$$= 16 \text{ ms}$$

$$P_3 = \frac{1000 \times 10^3}{2.5 \times 10^8}$$

$$= 4 \text{ ms}$$

$$\text{Total Prop delay} = P_1 + P_2 + P_3$$

$$= 40 \text{ ms}$$

$$\text{Total Delay} = (1) + (2) + (3)$$

$$= 64 + 40$$

$$= 64 \text{ ms total}$$

Chapter 2

Q1) True or false (Question Type)

Ans false - Because it sends 4 and receives 4

Q2) True or false (Question Type)

Ans True - Persistent HTTP leaves connection open

Q3) True or false

Ans false - Each TCP segment can only carry one request

Q4) True or false

Ans false - Date is request generation time

Q5) True or false

Ans false - 204 No Content

P2

The successive visit incur an RTT of RTT_2, \dots, RTT_n which is actually the total amount of time to get the IP Address from the DNS

$$[RTT_1 + RTT_2 + \dots + RTT_n]$$

- First of all, the connection will establish

-> one side client, other side server

~~After getting IP Address, two RTT are needed to receive the file since one RTT is used to~~

- When connection is made then RTT convert in 1 from 0, whenever client go for request then RTT will updated by 1 and event time RTT add one unit the connection will not close

that is why it total amount of RTT

$$[RTT_1 + RTT_2 + \dots + RTT_n]$$

- After getting the IP Address, two RTT are needed to receive the file since one RTT is used to set up the TCP connection and another RTT is used to request and receive the file

$$2RTT_0 + RTT_1 + RTT_2 + \dots + RTT_n$$
